

# Computer Networks

## Error Coding Overview (§3.2)

David Wetherall (djw@uw.edu)

Professor of Computer Science & Engineering

UNIVERSITY *of* WASHINGTON

# Topic

- Some bits will be received in error due to noise. What can we do?
  - Detect errors with codes »
  - Correct errors with codes »
  - Retransmit lost frames ← Later
- Reliability is a concern that cuts across the layers – we'll see it again

# Problem – Noise may flip received bits

# Approach – Add Redundancy

- Error detection codes
  - ➔ Add check bits to the message bits to let some errors be detected
- Error correction codes
  - ➔ Add more check bits to let some errors be corrected
- Key issue is now to structure the code to detect many errors with few check bits and modest computation

# Motivating Example

- A simple code to handle errors:
  - Send two copies! Error if different.

0 1 0 1

- How good is this code?
  - How many errors can it detect/correct?
  - How many errors will make it fail?

? 0  
1 1

# Motivating Example (2)

- We want to handle more errors with less overhead
  - Will look at better codes; they are applied mathematics
  - But, they can't handle all errors
  - And they focus on accidental errors (will look at secure hashes later)

# Using Error Codes

- Codeword consists of D data plus R check bits (=systematic block code)

- Sender:
  - Compute R check bits based on the D data bits; send the codeword of D+R bits

# Using Error Codes (2)

- Receiver:
  - Receive  $D+R$  bits with unknown errors
  - Recompute  $R$  check bits based on the  $D$  data bits; error if  $R$  doesn't match  $R'$

# Intuition for Error Codes

- For  $D$  data bits,  $R$  check bits:

- Randomly chosen codeword is unlikely to be correct; overhead is low  $\sim \frac{1}{2^R}$

# R.W. Hamming (1915-1998)

- Much early work on codes:
  - “Error Detecting and Error Correcting Codes”, BSTJ, 1950
- See also:
  - “You and Your Research”, 1986

# Hamming Distance

- Distance is the number of bit flips needed to change  $D_1^{xR}$  to  $D_2^{xR}$   
 $1 \rightarrow 111, 0 \rightarrow 000$  distance = 3
- Hamming distance of a code is the minimum distance between any pair of codewords  
HD = 3

# Hamming Distance (2)

- Error detection:
  - For a code of distance  $d+1$ , up to  $d$  errors will always be detected

$$d+1=3 \Rightarrow d=2$$

000      111

$$\begin{array}{cc} 001 & 010 \\ 100 & 011 \\ 101 & 110 \end{array}$$

# Hamming Distance (3)

- Error correction:
  - For a code of distance  $2d+1$ , up to  $d$  errors can always be corrected by mapping to the closest codeword

Handwritten notes illustrating error correction for a code with distance 3 ( $d=1$ ):

$HD=3$   $2d+1=3$   
 $d=1$

Diagram showing a received word  $000$  and a codeword  $110$  (circled). An arrow points from  $000$  to  $010$ , and another arrow points from  $110$  to  $111$ .
